

# Simple math for a complex world: Random walks in biology and finance

---

Jake Hofman  
Physics Department  
Columbia University  
2007.10.31

# Outline

---

- Complex systems
- The atomic hypothesis and Brownian motion
- Mathematics of random walks
- Random walks in biology
- Random walks in finance
- Conclusions

# Complex systems

---

It's difficult to model complex systems, even when we (think we) know the fundamental principles by which they are governed.

# Complex systems

We would also like to model systems for which fundamental principles are unknown (or may not exist)

# Complex systems

---

- **So how can we say anything meaningful, let alone *quantitative*, about these systems?**
  - Collective behavior of many random things can be quantified, even when behavior of individual things is random or unpredictable
  - Relatively simple mathematics; mostly probability and statistics
  - Many seemingly disparate systems united by mathematics

# The atomic hypothesis

---

# The atomic hypothesis

---

"Observe what happens when sunbeams are admitted into a building and shed light on its shadowy places. You will see a multitude of tiny particles mingling in a multitude of ways... their dancing is an actual indication of underlying movements of matter that are hidden from our sight... It originates with the atoms which move of themselves [i.e. spontaneously]. Then those small compound bodies that are least removed from the impetus of the atoms are set in motion by the impact of their invisible blows and in turn cannon against slightly larger bodies. So the movement mounts up from the atoms and gradually emerges to the level of our senses, so that those bodies are in motion that we see in sunbeams, moved by blows that remain invisible." - *On the Nature of Things*, Lucretius, 60 B.C.

## The size of a molecule

Ben Franklin finds that a teaspoon of oil covers the surface of a pond, half an acre in surface area; Lord Rayleigh calculates molecular size

A  
BRIEF ACCOUNT  
OF  
MICROSCOPICAL OBSERVATIONS

*Made in the Months of June, July, and August, 1827,*

ON THE PARTICLES CONTAINED IN THE  
POLLEN OF PLANTS;

AND

ON THE GENERAL EXISTENCE OF ACTIVE  
MOLECULES

IN ORGANIC AND INORGANIC BODIES.

BAVARIA, ETC.

<http://www.brianjford.com/wbbrowna.htm>

Robert Brown observes the “incessant dance” of pollen grains in 1827

## Brownian motion

Decades later, postulate that observed motion is due to frequent ( $10^{12}$  / sec) collisions with small molecules ( $10^{-3}$  \* size pollen)

<http://www.cs.princeton.edu/courses/archive/fall05/cos226/assignments/atomic.html>

Bachelier and Einstein to the rescue: Brownian motion is quantified as a “random walk” and falsifiable experiments are formed; results support atomic hypothesis

## Brownian motion

We observe rare and infrequent large displacements; see also: [http://nanoatlas.ifs.hr/images/brownian\\_motion\\_my.swf](http://nanoatlas.ifs.hr/images/brownian_motion_my.swf)

## Diffusion

Observe many particles and we see average or *expected* behavior

# Life at low Reynolds number

E. M. Purcell

Lyman Laboratory, Harvard University, Cambridge, Massachusetts 02138

(Received 12 June 1976)

## Reynolds number

Dimensional estimate of inertial and viscous forces characterizes motion in fluid as laminar or turbulent

## How cells swim

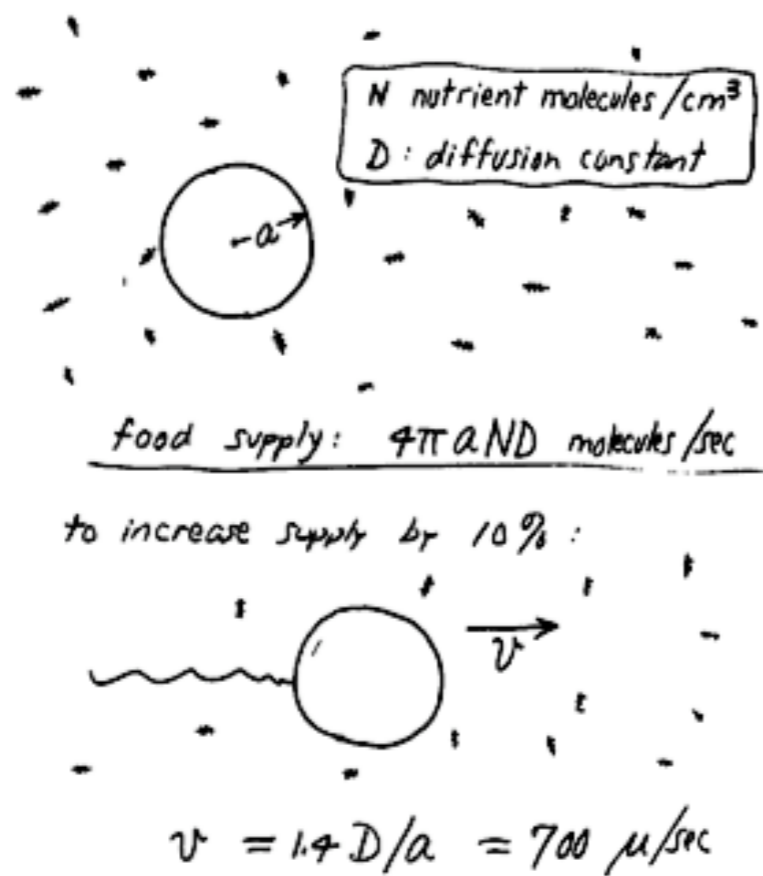

No coasting or turbulence in  
laminar flow  
E. coli evolved flagella to break  
symmetry

## How cells swim

No coasting or turbulence in laminar flow  
E. coli evolved flagella to break symmetry

## Why cells swim

Cells don't "outswim" diffusion;  
 Run and tumble mechanism is a  
 search for "greener pastures"

# Physical limits to biochemical signaling

William Bialek\* and Sima Setayeshgar†

Joseph Henry Laboratories of Physics and Lewis-Sigler Institute for Integrative Genomics, Princeton University, Princeton, NJ 08544

The analysis of bacterial chemotaxis by Berg and Purcell (6) provided a clear intuitive picture of the noise in “measuring” chemical concentrations. Their argument was that if we have a sensor with linear dimensions  $a$ , we expect to count an average of  $\bar{N} \sim \bar{c}a^3$  molecules when the mean concentration is  $\bar{c}$ . Each such measurement, however, is associated with a noise  $\delta N_1 \sim \sqrt{\bar{N}}$ . A volume with linear dimension  $a$  can be cleared by diffusion in a time  $\tau_D \sim a^2/D$ , so if we are willing to integrate over a time  $\tau$  we can make  $N_{\text{meas}} \sim \tau/\tau_D$  independent measurements, reducing the noise in our estimate of  $N$  by a factor of  $\sqrt{N_{\text{meas}}}$ . The result is that our fractional accuracy in measuring  $N$ , and hence in measuring the concentration  $c$  itself, is given by

$$\frac{\delta c}{\bar{c}} = \frac{\delta N}{\bar{N}} = \frac{1}{\sqrt{\bar{N} N_{\text{meas}}}} = \frac{1}{\sqrt{Da\bar{c}\tau}} \quad \text{[1]}$$

## Bacteria as molecule counters

count the molecules that regulate gene expression

count the interesting molecules in the environment

count the internal signaling molecules

How accurately can they count?  
Physical limits from:  
diffusion  
small size of receptor sites  
short time to average

E Coli perform close to these physical limits

Physics of chemoreception.

## Molecule counting in the first stages of fruit fly development

spatial structure in the adult organism results from spatial patterns of gene expression

mother puts messenger RNA for bicoid at (future) head of the embryo  
stain for bicoid protein

bicoid acts as a transcription factor to activate expression of hunchback  
stain for hunchback protein

this boundary is the first step in making the "segments" of the fly's body

how accurately can the boundaries be drawn?  
or, how precisely can the system measure bicoid concentration?  
what are the physical limits to counting bicoid molecules?

# Options pricing

What is the fair price for a contract to buy or sell a stock at a fixed price on a future date?

## Binomial options pricing

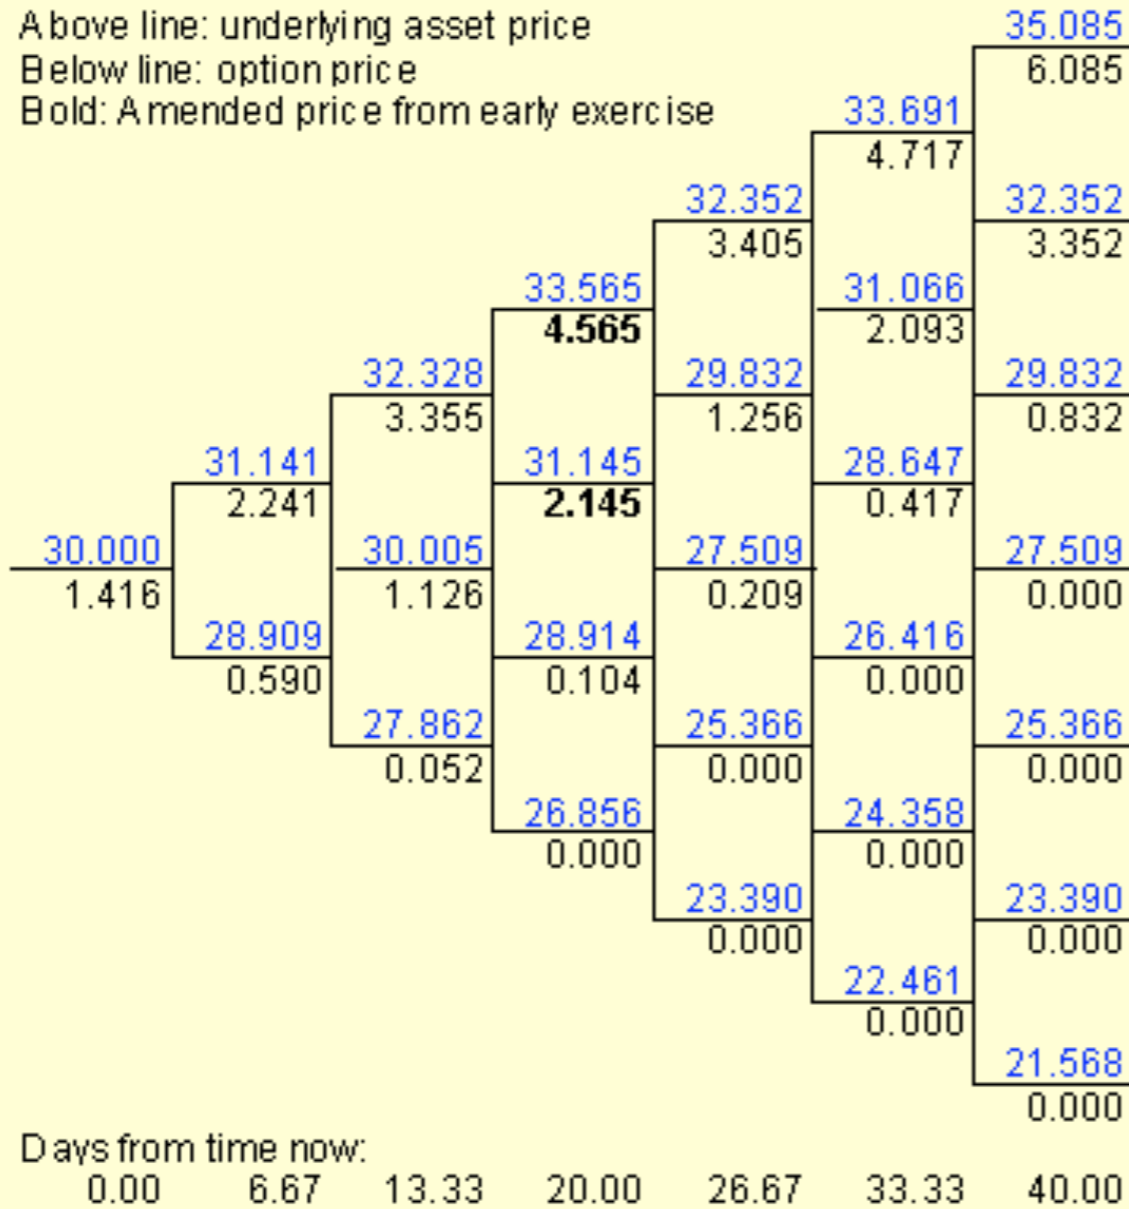

Geometric random walk:  
 Price of stock increases or decreases by *multiplicative* factor at each time step with *drift*

**Values at each node:**

Above line: underlying asset price

Below line: option price

Bold: Amended price from early exercise

# Binomial options pricing

Use geometric random walk to calculate final prices  
Work backwards to calculate fair option price at each time

<http://www.hoadley.net/options/binomialtree.aspx>

# Conclusions

---

- Simple mathematics, e.g. probability and statistics, describe complex processes
- Individual events are random or unpredictable, but collective behavior can be quantified reliably
- Mathematical framework of random walks give united description of diverse systems, e.g. molecular biology, financial markets, wireless networking, Google's PageRank
- Dimensional analysis useful for basic understanding of physical phenomena
